1. Intro

1.1. About this document

This document is the final laboration report of the course UMU54907 about deep learning . It introduces the subjects of RL (reinforcement learning) NLP (natural language processing) and GAN (generative adversarial networks)

The purpose of this document is mainly to gather the basic information about the subjects.

The document written in English except for the “uppgift” given by the teacher written in Swedish.
V 0.0 , 20190515

Intended audience.

The reader is expected to be a beginner in machine learning with some basic knowledge about python , jupyter , colab and machine learning .

Document summary

After a Introduction chapter in which the purpose of this lab is defined there will be one chapter per subject : RL , NLP , GAN ,

In the final chapter (Appendix) additional information such as some technical background or interesting references or model implementations are presented , ordered by subjects , in particular I did look at an implementation of real life cart_pole RL + DL presented in a blog of towards datascience

About the references

The explanation comes mostly from the book “deep_learning with python” Francois Cholet
in other cases the references is given

1.2. Uppgift Laboration 3

Intro

I Laboration 3 tänker jag att man ska prova lite mer avancerade saker inom Deep Learning. Vi hinner inte gå in på djupet men tänker att man nosar lite på 3 tekniker; Reinforcement Learning(RL), Hantering av naturligt språk (NLP) och Generativa nät (GAN).

Det kan ske genom att man testkör några program och ger sina kommentarer.

RL

Det handlar om att datorn lär sig saker genom att experimentera med sin omgivning; lite som barn eller djur lär sig tänker jag. Det bygger på att man får en belöning (reward) om man gör något bra i en viss situation (state) och straff om man gjort nåt dumt, förstärkt inläring. Det fina är alltså att datorn kan lära sig något där det inte finns någon lärare/facit, t ex spelet Go. Vi ska titta på ett reglerproblem; cart-pole, som bygger på att man ska balansera en pinne, kopplad via gångjärn på toppen av en liten (järnvägs)vagn, genom att köra/putta vagnen framåt eller bakåt. Spårets längd är också begränsat så man får straff om pinnen ramlar ner eller om man slår i ändpunkterna.

Målet är att få så mycket lycka (reward) som möjligt genom att hålla pinnen upprätt så länge som möjligt.

Här kommer vi köra lite från OpenAI's gym. Det är ett bibliotek med olika testmiljöer så man slipper programmera upp allt själv utan kan koncentrera sig på lärandet.

Vi kommer implementera situationerna som en tabell som fylls med inlärd värden (Q-värden) som talar om hur bra olika åtgärder (actions) är i just den situationen och då kan man ju välja den åtgärd som verkar bäst (exploit) i den situation man befinner sig i men ibland behöver man välja andra åtgärder för att lära sig mer om omgivningen, det kan ju finnas bättre som man inte vet om man aldrig provat (explore).

En mer avancerad variant (Deep RL) är att man ersätter situationstabellerna med Q-värden som neurala nät och då blir det lättare att interpolera mellan olika situationer och åtgärder men det blir också en del svårigheter.

NLP

Natural Language Processing, i det här fallet bygger på att orden får en vektor (embedding) med tal förknippade till sig. Dessa tal kan man få fram genom att datorn "läser" en massa text och hittar mönster i ordföljder. Talen representerar dimensioner i betydelsen av orden som kan liknas i t ex manlighet, mäktighet, naturlighet, fruktighet etc. Då kan man t ex räkna ut vad kung – man + kvinna är (drottning) och skapa mångdimensionella rymder där man kan se (med t ex tensorboard) hur orden hänger ihop med varandra och göra diverse analyser.

Det är vanligt att man använder återkopplade nät såsom RNN, LSTM och GRU för sådana här projekt.

Vi ska använda recensioner av filmer för att först lära sig vad som är goda respektive kritiska ord och sen gissa om andra filmer anses bra eller dåliga baserat på texten i recensionen.

En modern state-of-the-art metod är BERT som är rätt komplicerad men ger bättre resultat.

GAN

Bygger på att man har Två nät; dels ett, ”konstnären”, som genererar (skapar) data och sen ett annat nät ”konstkritikern” som bedömer hur bra verk konstnären åstadkommit. Målet för konstnären är förstås att få kritikern att inte se skillnad på sitt verk och andras mästerverk och kritikern över på att bli bättre och bättre på att skilja bra verk från dåliga.

Med denna konkurrens så blir båda näten bättre och bättre och fascinerande kreativa.

Vi ska använda en konstnär som ska konstruera siffror som ska bli förvillande lika äkta handskrivna siffror och kritikern ska lära sig att se skillnad på vad som är riktiga siffror och vad som är kråkfötter.

Utförande redovisning betyg

Du ska köra de 3 (+ ev några avancerade) tillhandahållna Python-programmen samt justera, modifiera och kommentera lite i koden så läraren kan se att du förstår vad som händer.

Grundversioner

RL: Cart-pole

Colab-Länk finns i Moodle:

https://colab.research.google.com/drive/1hOTmbBSiZS1Ea77_7iwwpayvcjLNDDfZ

Beskrivande kommentarer och källkod till Cart-pole-miljön

<https://gym.openai.com/envs/CartPole-v1/#id1>

https://github.com/openai/gym/blob/master/gym/envs/classic_control/cartpole.py

Uppgift RL: kör colab-versionen och förbättra och beskriv koden litegrann. Plotta ut hur mycket reward den får allteftersom för att visa om den blir bättre eller möjligen sämre? Testa med några olika parametervärden, t ex öka antalet episoder för att få den att lära sig bättre. Epsilon styr hur girig (exploit) den ska vara – om ett slumptal är under Epsilon så provar den ett slumpmässigt värde för att experimentera/lära sig.

Rewarden är hur många steps som den lyckas få pinnen att fortsätta stå upp, >180 räknas som mycket bra. Vilka 4 mätningar ingår i state-informationen som grund för om man ska putta till höger eller vänster?

NLP: Exempel 6.2 ur kursboken

<https://github.com/fchollet/deep-learning-with-python-notebooks>

GAN: Enkel GAN i Colab

Enkel GAN i Colab, TF2.0, del av Lab 3

<https://www.tensorflow.org/alpha/tutorials/generative/dcgan>

Avancerade versioner

RL: Deep RL

Modifiera någon parameter och kommentera lite i koden så läraren kan se att du förstår vad som händer.

NLP: BERT

blog to study is NLP: Contextualized word embeddings from BERT

<https://towardsdatascience.com/nlp-extract-contextualized-word-embeddings-from-bert-keras-tf-67ef29f60a7b>

Modifiera någon parameter och kommentera lite i koden så läraren kan se att du förstår vad som händer.

GAN:Kör 8.3-neural-style-transfer med en egen bild

Redovisning o Betyg

Skärmdumpar av körningar och dina kommentarer i en pdf-rapport på ca 3 - 5 sidor.

Kör man grundversionen av programmen och kommenterar vettigt får man G. Kör man en extra avancerad version får man VG och två avancerade versioner får man MVG.

1.3. My environment for programming and test

My local environment is a desktop (no GPU) running Ubuntu 18.04

the code is written in python . This lab involves python pgm run on localhost and colab , jupyter notebooks run on localhost and colab

Keras and tensor flow as backend where used.

The versions in local host

```
syll> python3 --version
```

```
Python 3.6.7
sylv1> jupyter --version
4.4.0
sylv1> python3 localW0.py
Using TensorFlow backend.
keras.__version__: 2.2.4
```

version and in colab:

```
! python --version
Python 3.6.7
! jupyter --version
4.4.0
import keras
Using TensorFlow backend.
print (keras.__version__)
2.2.4
import tensorflow as tf
tf.version.VERSION
'1.13.1'
```

I wonder if it is not a coincidence that the versions are the same .

1.4. About the files on gitHub

All files related to this lab (program code and this pdf document) are gathered at <https://github.com/SylGrafe/RepoDI01/lab3>

notice that just all files are gathered under the folder **lab3**

Notebooks and python files

As Colab is in a virtual environment without easy procedure to read and write files I decided to put all information in this pdf file lab3sygr0003.pdf

For nlp

lab3_nlp0.ipynb original file (without any additional comments)

lab3_nlp1.ipynb copy from Pre-trained BERT contextualized word embeddings (without any additional comments)

lab3_nlp2.ipynb copy from Predicting Movie Reviews with BERT on TF Hub.ipynb

I did not really study this code I wanted just to see how well the model was performing on the well known problem of predicting movie review .

for gan

lab3_gan0.ipynb the original program to study (without any additional comments)

for rl

lrl_prorok.py original file from Kalle prorok for rl

lab3_rl0.py a modified version of rl_prorok.py (with some additional comments)

lab3_cartpolev1.py which define the environment cartpole1 (without any additional comments)

2. Reinforcement Learning , RL0

2.1. Preliminaries

This section is an introduction of Reinforcement Learning (RL). . The aim is to use the cart_pole environment to learn more about RL

The original programs to study are lab3_rl_prorok and lab3_cartpolev1.

lab3_cartpolev1.py Classic cart-pole system implemented by Rich Sutton et al.

lab3_rl_prorok.py : the original pgm written by Kalle Prorok to implement RL

lab3_rl0.py is a modified version of rl_Prorok that I did implement,

gym first steps

In order to use the simulated environment for cartpole it was necessary to install gym.

Details about the installation are presented in the annexe I nthe RL section.

2.2. lab3_rl programs

Analyse rl_Prorok.py

Using q tables the pgm try the choose the best actions in order to keep the pole into acceptable positions .

The same procedure is run several time and this is the description of one run:

At each step in a given run

qtable are updated in order to remember which states give the best estimated final values.

If the estimated final value for a state is already know and if the pgm is “greedy ” then the pgm will use the best action

Sometimes the pgm is not greedy and will **explore** , it chooses use a random action instead of choosing the best value according to the qtable. The parameter epsilon control how often a random action is taken

A run finishes when the environment evaluate that the cart or the pole are outside given limits.

Notice that the environment always return a reward of 1 until the run is finished so counting the **accumulated rewards** is the same that saying how many steps the pole and the cart had acceptable values .

make_state

Each state observation consist of 4 float defines in cartPolev1.py

Num	Observation	Min	Max
0	Cart Position	-4.8	4.8
1	Cart Velocity	-Inf	Inf
2	Pole Angle	-24 deg	24 deg
3	Pole Velocity At Tip	-Inf	Inf

the method make_state () transform this tulpe of 4 float into a single integer . This is necessary to order to bee able to be able to build a qtable where each state is a element.

Qtable

With DISCRETE_STEPS==10 there are 10000 elements in qtables each element contains the qvalues for this state . In other word

qtable[sti][0] estimation of Value for action 0 (left) and state sti

qtable[sti][1] estimation of Value for action 1 (right) and state sti

```
# Q-table for the discretized states, and two actions
num_states = DISCRETE_STEPS ** 4
qtable = [[0., 0.] for state in range(num_states)]
```

plot results

The results varies greatly from run to run

Results of one program run (with 1000 episodes) are presented here.

The results of 10 runs are plotted , one each 100 episode

It illustrate quite well the facts that program does not seem to learn evenly

lab3_rl0.py

This program is a modified version of rl_prorok.py and the main differences are

To evaluate the learning the **mean accumulated average** and the **ratio of good runs** are considered. A good run get a accumulated rewards of 180 (accumulated rewards == nb of steps before a run ends so it is also the nb of steps when the pole and the cart are in 'acceptable' state)

The **epsilon value is adjusted** to get it smaller when the pgm seems to have learn already well.

A new parameter **useRandom** was tested . it determine which action to choose when qvalues are equals: when useRandom is true choose action as random instead of choosing always left as it is the case otherwise.

It is addictive to run the pgm and try to get the best hyper parameters. It seems that there is not easy solution. I made many runs and presents here just some results

results

In the comment of the presented results I will use the following abbreviations:

MEAR = Mean average accumulated rewards

RGR = ration of good run

As text

List the average of accumulated rewards and ration of good run . The reason to present this text is to notice when epsilon value was changed. A time stampl identify the run and is also visible in the titles of in the plots presented afterwards in order to link a list to a plot.

((getting better))

The training finishes with a MEAR 131 , RGR 13% that is not too bad.

```
syll> python3 lab_rl0.py
Check at , av_value, good_count_ratio
1000 , 12, 0
2000 , 12, 0
```

```

2000 -----> myEpsilon:0.15
3000 , 22, 0
4000 , 36, 0

9000 -----> myEpsilon:0.02
10000 , 201, 76
2105_172413 epsi , start0.10 [0.02,0.15]
```

```
lr: 0.02 , random: True
```

```
good_run (val: 180 , Limit:166)
```

plots

The corresponding plots are shown , all at once for better comparision

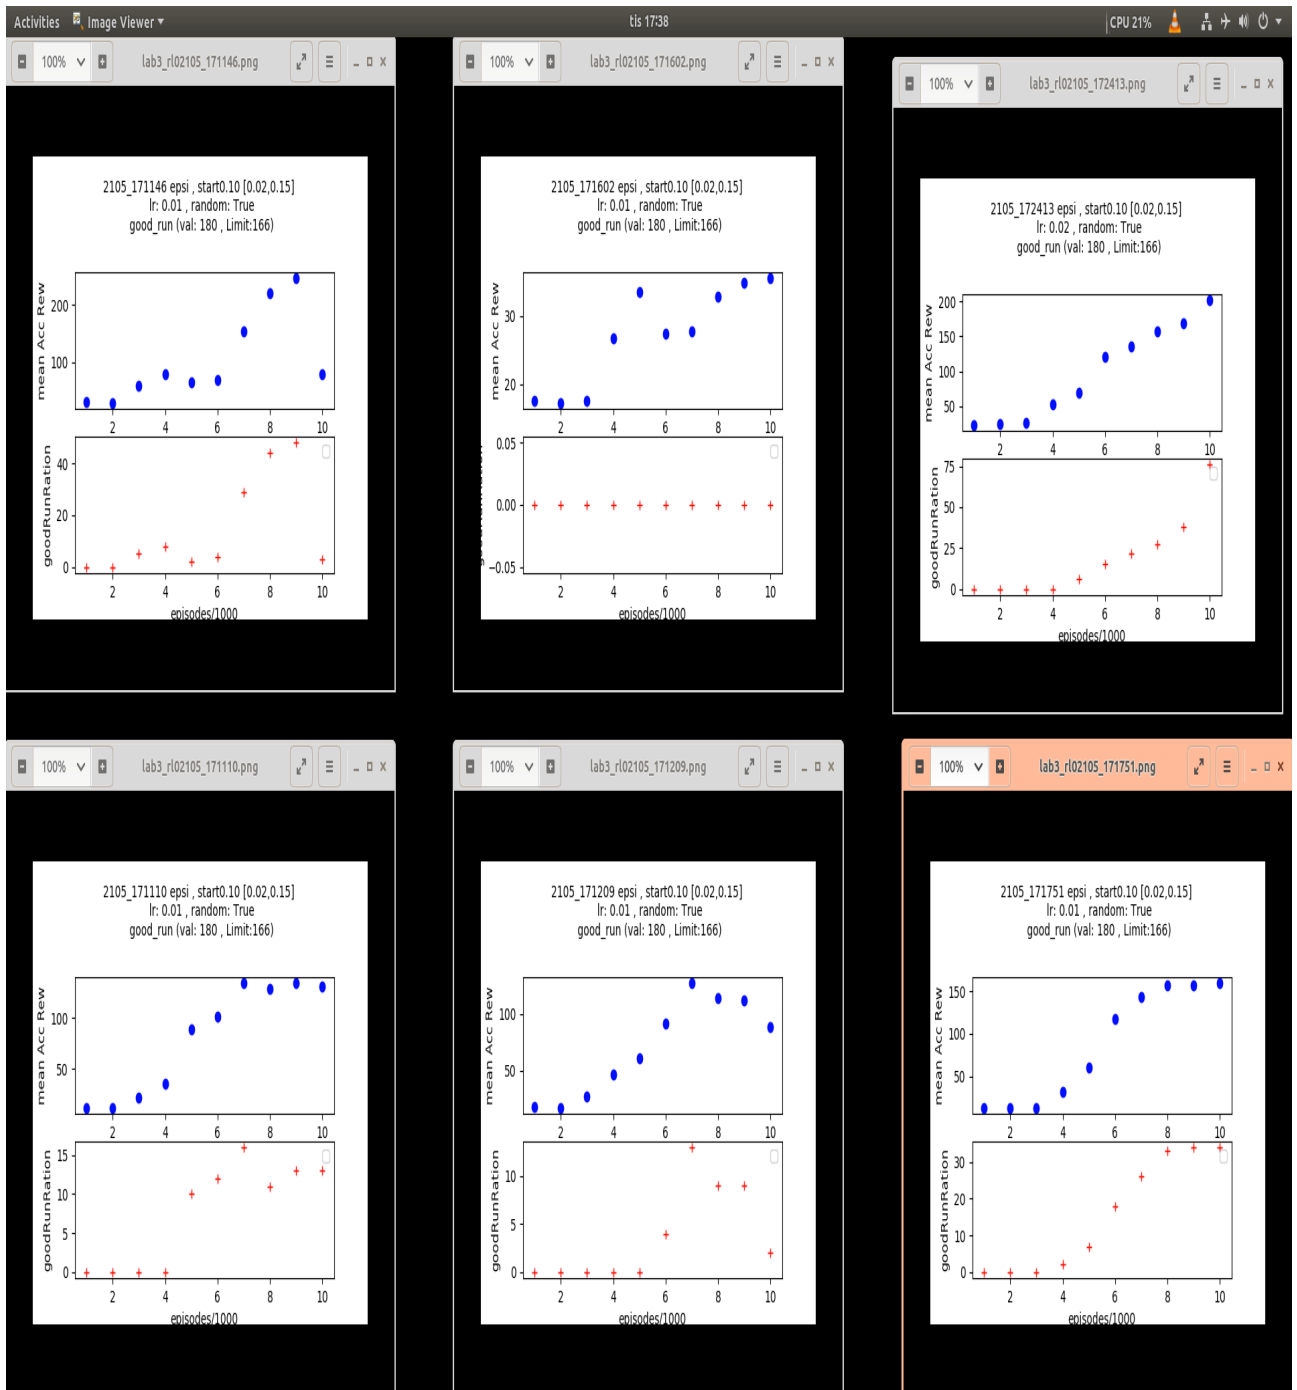

Illustration 1: mean accumulated rewards and good run ratios

3. Natural Language Processing NLP

NLP0 study Cholets example 6.2

Intro

The aim of this part of the laboration is an introduction to NLP = naturel language processing.

The purpose is to study this code

6.2-understanding-recurrent-neural-networks.py , from the course book (Cholet) to be found at

Ref: <https://github.com/fchollet/deep-learning-with-python-notebooks>

This code has been copied in lab3_nlp0.ipynb and run in colab

problem definition

IMDB sentiment--classification task . The model must be able to classify movie reviews as positives or negatives.

kort analyse

The problem can be solved by using simple densely connected model or by using Embedding layer and RNN.

By using embedding you create a word encoding in a space in which the words are related in order to reflect the structure of the language,

By using RNN you take into account the sequence (meaning that the position on the words in the text is relevant to solve the problem)

lab3_nlp0.ipynb

Three models are implemented in lab3_nlp0:

model0 a simple a RNN

model1 one lstm layer

model00 as a reference is a model with only densely connected layers (3 total)

the training curves are included in this document,

code extract

An extract of the code about the data processing and the implementation of model1 is given here

```

max_features=10000
maxlen=500
(input_train, y_train), (input_test, y_test) = imdb.load_data(num_words=max_features)
input_train = sequence.pad_sequences(input_train, maxlen=maxlen)
input_test = sequence.pad_sequences(input_test, maxlen=maxlen)
model1 = Sequential()
model1.add(Embedding(max_features, 32))
model1.add(LSTM(32))
model1.add(Dense(1, activation='sigmoid'))

model1.compile(optimizer='rmsprop',
               loss='binary_crossentropy',
               metrics=['acc'])

print ("\nlab3_nlp0 train model1 : Embedd (maxFeat , 32 ) + LSTM(32) ")
hist1 = model1.fit(input_train, y_train,
                  epochs=myEpochs,
                  batch_size=128,
                  verbose=1 ,
                  validation_split=0.2)

```

More information about this code is given in the technical background section to be found in the Annexe.

trainings curves

The corresponding training curves seems to indicate that lstm is slightly better than other models

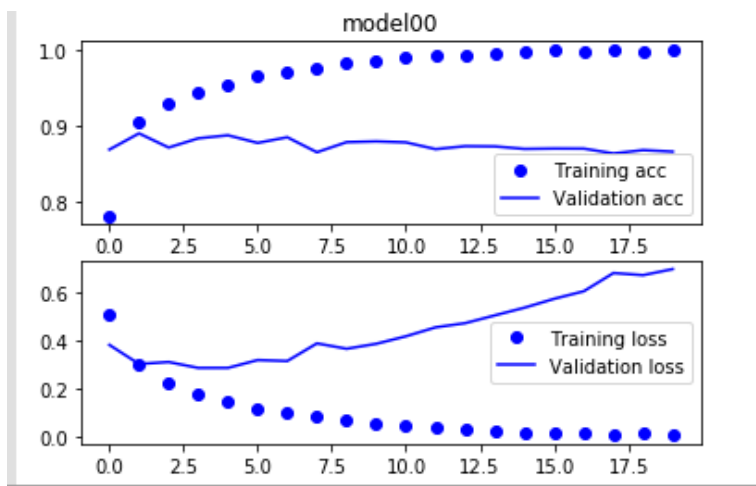

Illustration 2: nlp0 , training Model00 (dense only)

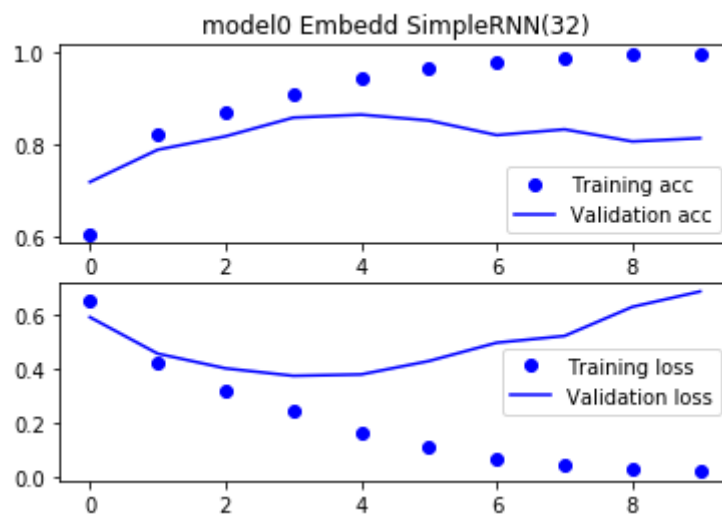

Illustration 3: nlp0 training model0 : RNN

Illustration 4: nlp0 , training model1 (lstm)

All curves shows that the models overfitt rapidly. lstm seem to be only slightly better than a model with only densely connected layers. Lstm training loss is noisy ,

As usual lstm has much more computational cost

(see computational cost in the annex)

3.1. NLP1 , BERT

Intro

The aim is to study a code that extracts contextualized word embeddings from BERT . The code is found at:

<https://towardsdatascience.com/nlp-extract-contextualized-word-embeddings-from-bert-keras-tf-67ef29f60a7b>

BERT means Bidirectional Encoder Representations from Transformer

More information about Bert , transformer and about tensor flow estimator is given in the annex section NL. In particular some extracts from a really good introduction to BERT

(from ai.googleblog.com) are given

about lab3_nlp1

The code to study has been copied into lab3_nlp1.ipynb and run in colab using TPU.

The code is really hard to understand.

It is an example of loading pretrained BERT models from checkpoints in order to produce contextualized word embeddings. Such an embedding is calculated for a test sentence at the end of the code,

Note: I did remove the authentication part `auth.authenticate_user()` and the pgm seem to run anyway , nice!

To try to understand the code I look at it in reverse

final embedding

the final lines of code are illustrate the embedding obtain for the test sentence :

“learning requires patience”

```
mmbbeddings = get_features(["learning requires patience"])
```

```

print("len(embeddings)" , len(embeddings) )
print("type(embeddings)" , type(embeddings) )
for i , k in enumerate( embeddings ) :
    if i == 1 :
        print (k)
ii=0
for k ,v in embeddings.items () :
    print ("word %s , nb of floats :%d " % (k , len( v )))

```

and give this output

```

len(embeddings) 5
type(embeddings) <class 'collections.OrderedDict'>
learning
word [CLS] , nb of floats :768
word learning , nb of floats :768
word requires , nb of floats :768
word patience , nb of floats :768
word [SEP] , nb of floats :768

```

each words of the test sentence are encoded as a vector of length 768 a quite high dimension in my eyes, In the embedding we recognize CLS and SEP , some special tokens used for fine-tuning and specific task training.

Citat from the article:

<<[CLS] : The first token of every sequence. A classification token which is normally used in conjunction with a softmax layer for classification tasks. For anything else, it can be safely ignored.

[SEP] : A sequence delimiter token which was used at pre-training for sequence-pair tasks (i.e. Next sentence prediction). Must be used when sequence pair tasks are required. When a single sequence is used it is just appended at the end.>>

About model_fn

model_fn seems to be used to make predictions via an estimator .

from code extracts you notice that the features comes from Bert :

```

def model_fn_builder(bert_config, init_checkpoint, layer_indexes, use_tpu,
                    use_one_hot_embeddings):
    """Returns `model_fn` closure for TPUEstimator."""

```

```

def model_fn(features, labels, mode, params): # pylint: disable=unused-argument
    """The `model_fn` for TPUEstimator."""

    ...

    model = modeling.BertModel(
        config=bert_config,
        is_training=False,
        input_ids=input_ids,
        input_mask=input_mask,
        token_type_ids=input_type_ids,
        use_one_hot_embeddings=use_one_hot_embeddings)

    ...

    all_layers = model.get_all_encoder_layers()

    ...

    for (i, layer_index) in enumerate(layer_indexes):
        predictions["layer_output_%d" % i] = all_layers[layer_index]

    ....

    output_spec = tf.contrib.tpu.TPUEstimatorSpec(
        mode=mode, predictions=predictions, scaffold_fn=scaffold_fn)

    return output_spec

return model_fn

```

only predictions

The model is used d to make predictions (no training is involved) as seen in this code extract

```

def model_fn(features, labels, mode, params): # pylint: disable=unused-argument
    """The `model_fn` for TPUEstimator."""

    ...

    if mode != tf.estimator.ModeKeys.PREDICT:
        raise ValueError("Only PREDICT modes are supported: %s" % (mode))

```

And from this code extract you understand that the model is build from checkpoints

```

INIT_CHECKPOINT = BERT_PRETRAINED_DIR + '/bert_model.ckpt'
...
def get_features(input_text, dim=768):
    ...
    model_fn = model_fn_builder(
        bert_config=bert_config,
        init_checkpoint=INIT_CHECKPOINT,
        layer_indexes=layer_indexes,
        use_tpu=True,
        use_one_hot_embeddings=True)
    ...
    return output

```

4. Generative Adversarial Networks GAN0

4.1. *intro*

Generative adversarial networks GAN can be used to create pictures.

The tutorial demonstrates how to generate images of handwritten digits using a GAN.

The code to study is defined in

<https://colab.research.google.com/github/tensorflow/docs/blob/master/site/en/r2/tutorials/generative/dcgan.ipynb>

lab3_gan0 is a copy of dcgan.ipynb that was run in colab with gpu .

4.2. *Brief presentation of the code*

Two models are trained simultaneously by an adversarial process. A **generator** ("the artist") learns to create images that look real, while a **discriminator** ("the art critic") learns to tell real images apart from fakes. During training, the **generator** progressively becomes better at creating images that look real, while the **discriminator** becomes better at telling them apart. The process reaches equilibrium when the **discriminator** can no longer distinguish real images from fakes.

The code for GAN is quite complicated , in this section I present the most relevant extract from the code

generator

Looking at the code of the generator model I notice BatchNormalization , LeakyRelu and Conv2DTranspose more information about these functions is presented in the annexe

```
def make_generator_model():
    model = tf.keras.Sequential()
    model.add(layers.Dense(7*7*256, use_bias=False, input_shape=(100,)))
    model.add(layers.BatchNormalization())
    model.add(layers.LeakyReLU())
    model.add(layers.Reshape((7, 7, 256)))
    assert model.output_shape == (None, 7, 7, 256) # Note: None is the batch size
    model.add(layers.Conv2DTranspose(128, (5, 5), strides=(1, 1), padding='same', use_bias=False))
    assert model.output_shape == (None, 7, 7, 128)
    model.add(layers.BatchNormalization())
    model.add(layers.LeakyReLU())
    model.add(layers.Conv2DTranspose(64, (5, 5), strides=(2, 2), padding='same', use_bias=False))
    assert model.output_shape == (None, 14, 14, 64)
    model.add(layers.BatchNormalization())
    model.add(layers.LeakyReLU())
    model.add(layers.Conv2DTranspose(1, (5, 5), strides=(2, 2), padding='same', use_bias=False, activation='tanh'))
    assert model.output_shape == (None, 28, 28, 1)
    return model
...
generator=make_generator_model()
```

the discriminator

The code for the discriminator is more familiar and look like a typical CNN.

```
def make_discriminator_model():
    model = tf.keras.Sequential()
    model.add(layers.Conv2D(64, (5, 5), strides=(2, 2), padding='same', input_shape=[28, 28, 1]))
    model.add(layers.LeakyReLU())
    model.add(layers.Dropout(0.3))
    model.add(layers.Conv2D(128, (5, 5), strides=(2, 2), padding='same'))
    model.add(layers.LeakyReLU())
    model.add(layers.Dropout(0.3))
    model.add(layers.Flatten())
    model.add(layers.Dense(1))
```

```

return model

...
discriminator=make_discriminator_model()
...

```

Model training

The “heart of the matter” for model training is defined in the module `train_step` where you can see that both generator and discriminator are called

```

def train_step(images):
    noise = tf.random.normal([BATCH_SIZE, noise_dim])
    with tf.GradientTape() as gen_tape, tf.GradientTape() as disc_tape:

        generated_images = generator(noise, training=True)
        real_output = discriminator(images, training=True)
        fake_output = discriminator(generated_images, training=True)

        gen_loss = generator_loss(fake_output)
        disc_loss = discriminator_loss(real_output, fake_output)

        gradients_of_generator = gen_tape.gradient(gen_loss, generator.trainable_variables)
        gradients_of_discriminator = disc_tape.gradient(disc_loss, discriminator.trainable_variables)

        generator_optimizer.apply_gradients(zip(gradients_of_generator, generator.trainable_variables))
        discriminator_optimizer.apply_gradients(zip(gradients_of_discriminator, discriminator.trainable_variables))
    ...

```

`train_step` is then called in the `train` method an extract on this is presented now

```

def train(dataset, epochs):
    for epoch in range(epochs):
        start = time.time()
        for image_batch in dataset:
            train_step(image_batch)
        # Produce images for the GIF as we go    display.clear_output(wait=True)
        generate_and_save_images(generator,    epoch + 1,    seed)
        # Save the model every 15 epochs

```

```
if (epoch + 1) % 15 == 0:
```

```
    checkpoint.save(file_prefix = checkpoint_prefix)
```

```
    print ('Time for epoch {} is {} sec'.format(epoch + 1, time.time()-start))
```

```
# Generate after the final epoch
```

```
display.clear_output(wait=True)
```

```
generate_and_save_images(generator, epochs, seed)
```

4.3. Some images produced under training

Some images produced by `generate_and_save_images(model, epoch, test_input)` are presented now to illustrate how the generator gets better and better to produce reliable digits

Illustration 5: images at epoch1

Illustration 6: gan0 images at epoch 20

Illustration 7: gan0 images at epoch 40

Illustration 8: gan0 images at epoch 50

5. Annexe

More info about the different subjects is gathered in this section

5.1. RL

about gym

<https://github.com/openai/gym/wiki/Environments>

An environment is a problem with a minimal interface that an agent can interact with. The environments in the OpenAI Gym are designed in order to allow objective testing and benchmarking of an agents abilities.

Install gym

```
syl1> pip3 install --user gym
```

Collecting gym

cartpole-v0 first run

<http://gym.openai.com/docs/>

CartPole-v0 belongs to Classic control and toy text and is like a hello world pgm to learn about gym and to learn about RL.

The aim of the game is to learn which movement to apply to the cart in order to have the pole vertically above the cart. In the first demo random movements (left or rights) are applied to the

cart and the pole never manage to get to and keep the wanted position so the game is over very rapidly

Here's a bare minimum example of getting something running. This will run an instance of the CartPole-v0 environment for 1000 timesteps, rendering the environment at each step. You should see a window pop up rendering the classic cart-pole problem:

Here is the python code:

```
syl1> cat gym1.py
import gym
from gym import envs
env = gym.make('CartPole-v0')
env.reset()
for _ in range(1000):
    env.render()
    env.step(env.action_space.sample()) # take a random action
env.close()
```

`env.render()` will produce a popup window containing the animated cartpole. The cart is running randomly on the horizontal line and the pole is under the cart, the whole window disappears within seconds.

Notions about RL

A Beginner's Guide to Deep Reinforcement Learning

<https://skymind.ai/wiki/deep-reinforcement-learning>

I found this article from skymind about RL extremely well written and interesting :

In this extract some notions are presented in particular : q-value , exploit and explore.

Reinforcement learning refers to **goal-oriented algorithms**, which learn how to attain a complex objective (goal) or maximize along a particular dimension over many steps;

...

Reinforcement learning solves the difficult problem of **correlating immediate actions with the delayed returns they produce**.

...

Reinforcement learning can be understood using the concepts of **agents, environments, states, actions and rewards**, all of which we'll explain below.

...

So environments are functions that transform an action taken in the current state into the next state and a reward; agents are functions that transform the new state and reward into the next action. We can know the agent's function, **but we cannot know the function of the environment**. It is a black box where we only see the inputs and outputs.

....

Reinforcement learning represents an **agent's attempt to approximate the environment's function**, such that we can send actions into the black-box environment that maximize the rewards it spits out.

...

Value (V): The expected long-term return with discount, as opposed to the short-term reward R. $V_{\pi}(s)$ is defined as the expected long-term return of the current state under policy π . We discount rewards, or lower their estimated value, the further into the future they occur. See discount factor. And remember Keynes: "In the long run, we are all dead." That's why you discount future rewards.

Q-value or action-value (Q): Q-value is similar to Value, except that it takes an extra parameter, the current action a. $Q_{\pi}(s, a)$ refers to the long-term return of the current state s, taking action a under policy π . Q maps state-action pairs to rewards. Note the difference between Q and policy.

...

The goal of reinforcement learning is to pick the best known action for any given state, which means the actions have to be ranked, and assigned values relative to one another. Since those actions are state-dependent, what we are really gauging is the value of state-action pairs; i.e. an action taken from a certain state, something you did somewhere.

...

We map state-action pairs to the values we expect them to produce with the Q function, described above. The Q function takes as its input an agent's state and action, and maps them to probable rewards.

Reinforcement learning is the process of **running the agent through sequences of state-action pairs, observing the rewards that result, and adapting the predictions of the Q function to those rewards** until it accurately predicts the best path for the agent to take. That prediction is known as a policy.

...

After a little time spent employing something like a Markov decision process to **approximate the probability distribution of reward** over state-action pairs, a reinforcement learning algorithm may tend to repeat actions that lead to reward and cease to test alternatives. There is a tension between the exploitation of known rewards, and continued exploration to discover new actions that also lead to victory.

...

reinforcement learning algorithms can be made to both **exploit** and **explore** to varying degrees, in order to ensure that they don't pass over rewarding actions at the expense of known winners.

...

Where do neural networks fit in? **Neural networks are the agent that learns to map state-action pairs to rewards**. Like all neural networks, they use coefficients to approximate the function relating inputs to outputs, and their learning consists to finding the right coefficients, or weights, by iteratively adjusting those weights along gradients that promise less error.

...

At the beginning of reinforcement learning, the neural network coefficients may be initialized stochastically, or randomly. Using feedback from the environment, the neural net can use the difference between its expected reward and the ground-truth reward to adjust its weights and improve its interpretation of state-action pairs.

...

Like human beings, the **Q function is recursive**. Just as calling the wetware method human() contains within it another method human(), of which we are all the fruit, calling the Q function on a given state-action pair requires us to call a nested Q function to predict the value of the next state, which in turn depends on the Q function of the state after that, and so forth.

Reinforcement Learning and DQN, learning to play from pixels

<https://rubenfiszel.github.io/posts/r14j/2016-08-24-Reinforcement-Learning-and-DQN.html>

Posted on August 24, 2016 by Ruben Fiszel

I like this article in particular the explanations about experience replay. Experience replay is in use in the model presented as “real life with cart-pole”

Experience replay

There is one issue with using neural network as Q approximator. **The transitions are very correlated.** This reduce the overall variance of the transition. After all, they are all extracted from the same episode. Imagine if you had to learn a task without any memory (not even short-term), you would always optimise your learning based on the last episode.

The Google DeepMind research team used experience replay, which is a windowed buffer of the last N transitions (N being a million in the original paper) with DQN and greatly improved their performances on atari. Instead of updating from the last transition, **you store it inside the experience replay and update from a batch of randomly sampled transitions from the same experience replay.**

Real life cart-pole RL and DL

A Real life cart pole with real RL is presented in this blog :

<https://towardsdatascience.com/cartpole-introduction-to-reinforcement-learning-ed0eb5b58288>

A real installation is filmed (rail cart and pole) and you see some training session and then the final results where the agent has learned to maintain the pole vertically above the cart, it is really impressive. The blog is also really interesting. and I decided to study the code a bit closer and try to understand (I did not understand so well)

description of the program

The model is trained with a densely connected network.

The code is found here: <https://github.com/gsurma/cartpole>

two main python pgm are involved: cartpole.py and score_logger.py

cartpole.py define the class DQNSolver

DQN (Deep Q network) is a RL technique that is aimed at choosing the best action for given circumstances (observation). Each possible action for each possible observation has its Q value, where 'Q' stands for a quality of a given move.

And DQNSolver implement a densely connected model

```
self.model = Sequential()
self.model.add(Dense(24, input_shape=(observation_space,), activation="relu"))
self.model.add(Dense(24, activation="relu"))
self.model.add(Dense(self.action_space, activation="linear"))
self.model.compile(loss="mse", optimizer=Adam(lr=LEARNING_RATE))
```

cartpole.py is the implementation of the agent , model.predict and model.fit are called in the code. Predict is used for action as you could guess:

```
def act(self, state):
    if np.random.rand() < self.exploration_rate:
        return random.randrange(self.action_space)
    q_values = self.model.predict(state)
    return np.argmax(q_values[0])
```

I found it hard to understand the function experience_replay () , notice that both predict and fit are called from this function

```
def experience_replay(self):
    if len(self.memory) < BATCH_SIZE:
        return
    batch = random.sample(self.memory, BATCH_SIZE)
    for state, action, reward, state_next, terminal in batch:
        q_update = reward
        if not terminal:
            q_update = (reward + GAMMA * np.amax(self.model.predict(state_next)[0]))
        q_values = self.model.predict(state)
        q_values[0][action] = q_update
        self.model.fit(state, q_values, verbose=0)
    self.exploration_rate *= EXPLORATION_DECAY
    self.exploration_rate = max(EXPLORATION_MIN, self.exploration_rate)
```

the pgm exit when the score satisfy a given condition defined in this extract from score_logger.py

```
def add_score(self, score, run):
    self._save_csv(SCORES_CSV_PATH, score)

    if mean_score >= AVERAGE_SCORE_TO_SOLVE and len(self.scores) >=
CONSECUTIVE_RUNS_TO_SOLVE:
        solve_score = run-CONSECUTIVE_RUNS_TO_SOLVE
```

running cartpole , program is learning !!

Running cartpole.py on local host (no more real life cart pole)

produces a list similar to lab3_rl0.py

but the score show the the program is really learning to control the pole.

```
syll1> python3 cartpole.py
```

5.2. NL

About lab3_nlp0

technical background

imdb dataset , imdb.load_data

ref: <https://keras.io/datasets/>

Dataset of movies reviews from IMDB, labeled by sentiment (positive/negative).

The reviews (sequences of words) have been turned into sequences of integers, where each integer stands for a specific word in a dictionary. For convenience, words are **indexed by overall frequency in the dataset**, so that for instance the integer "3" encodes the 3rd most frequent word in the data. This allows for quick filtering operations such as: "only consider the top 10,000 most common words, but eliminate the top 20 most common words".

```
(input_train, y_train), (input_test, y_test) = imdb.load_data(num_words=max_features)
```

num_words: integer or None. Top most frequent words to consider. Any less frequent word will appear as oov_char value in the sequence data.

pad_sequences

ref: <https://keras.io/preprocessing/sequence/>

```
keras.preprocessing.sequence.pad_sequences(sequences, maxlen=None, dtype='int32',  
padding='pre', truncating='pre', value=0.0)
```

This function transforms a list of num_samples sequences (lists of integers) **into a 2D Numpy array of shape (num_samples, num_timesteps)**. num_timesteps is either the maxlen argument if provided, or the length of the longest sequence otherwise.

conclusion on data preprocessing :

By using pad_sequence you can transform each review as a time steps with 500 elements (each element is an integer) to be fed into the embedding layer.

apropos embedding

ref Cholet ch06 : Word embeddings are dense, relatively lowdimensional, and learned from data.

It's reasonable to learn a new embedding space with every new task.

The Embedding layer takes at least two arguments: the number of possible tokens and the dimensionality of the embeddings .

The Embedding layer is best understood as a dictionary that maps integer indices (which stand for specific words) to dense vectors. It takes integers as input, it looks up these integers in an internal dictionary, and it returns the associated vectors. It's effectively a dictionary lookup

Because of I do not know what it was not possible any more to load the imdb database

<https://stackoverflow.com/questions/55890813/how-to-fix-object-arrays-cannot-be-loaded-when-allow-pickle-false-for-imdb-loa>

```
!pip install numpy==1.16.1

```

about Bert

Bert intro

<https://ai.googleblog.com/2018/11/open-sourcing-bert-state-of-art-pre.html>

I found the article extremely well written and gives here some extracts:

One of the biggest challenges in natural language processing (NLP) is the **shortage of training data**. Because NLP is a diversified field with many distinct tasks, most task-specific datasets contain only a few thousand or a few hundred thousand human-labeled training examples. However, modern deep learning-based NLP models see benefits from much larger amounts of data, improving when trained on millions, or billions, of annotated training examples. To help close this gap in data, researchers have developed a variety of **techniques for training general purpose language representation models** using the enormous amount of unannotated text on the web (known as pre-training). The pre-trained model can then be fine-tuned on small-data NLP tasks like question answering and sentiment analysis, resulting in substantial accuracy improvements compared to

training on these datasets from scratch.

...

BERT builds upon recent work in pre-training contextual representations — including Semi-supervised Sequence Learning, Generative Pre-Training, ELMo, and ULMFit. However, unlike these previous models, **BERT is the first deeply bidirectional, unsupervised language representation**, pre-trained using only a plain text corpus (in this case, Wikipedia).

Why does this matter? Pre-trained representations can either be **context-free or contextual**, and contextual representations can further be **unidirectional or bidirectional**. Context-free models such as word2vec or GloVe generate a single word embedding representation for each word in the vocabulary. For example, the word “bank” would have the same context-free representation in “bank account” and “bank of the river.” Contextual models instead generate a representation of each word that is based on the other words in the sentence. For example, in the sentence “I accessed the bank account,” a unidirectional contextual model would represent “bank” based on “I accessed the” but not “account.” *However, BERT represents “bank” using both its previous and next context* — “I accessed the ... account” — starting from the very bottom of a deep neural network, making it deeply bidirectional.

BERT Explained

The blog BERT Explained: State of the art language model for NLP give some more explanations about Bert.

<https://towardsdatascience.com/bert-explained-state-of-the-art-language-model-for-nlp-f8b21a9b6270>

How BERT works

BERT makes use of Transformer, an attention mechanism that learns contextual relations between words (or sub-words) in a text. In its vanilla form, Transformer includes two separate mechanisms —an encoder that reads the text input and a decoder that produces a prediction for the task. Since BERT’s goal is to generate a language model, only the encoder mechanism is necessary. The detailed workings of Transformer are described in a paper by Google.

...

When training language models, there is a **challenge of defining a prediction goal**. Many models **predict the next word in a sequence** (e.g. “The child came home from ____”), a directional approach which inherently limits context learning. To overcome this challenge, BERT uses two training strategies:

Masked LM (MLM) ...

Next Sentence Prediction (NSP) ...

About how to use Bert:

In this approach, a pre-trained neural network produces word embeddings which are then used as features in NLP models.

A guide to simple text classification with bert

<https://mc.ai/a-guide-to-simple-text-classification-with-bert/>

This article gives good explanations with simple words

About Transformer

Bert is a Transformer so what is a transformer ?

Extract from A Novel Neural Network Architecture for Language Understanding

<https://ai.googleblog.com/2017/08/transformer-novel-neural-network.html>

...

In contrast, the Transformer only performs a small, constant number of steps (chosen empirically). In each step, it applies a self-attention mechanism which **directly models relationships between all words in a sentence, regardless of their respective position**. In the earlier example “I arrived at the bank after crossing the river”, to determine that the word “bank” refers to the shore of a river and not a financial institution, the Transformer can learn to immediately attend to the word “river” and make this decision in a single step. In fact, in our English-French translation model we observe exactly this behavior.

About estimator

Estimator is used in lab3_nlp1

<https://towardsdatascience.com/first-contact-with-tensorflow-estimator-69a5e072998d>

“TensorFlow’s high-level machine learning API (tf.estimator) makes it easy to configure, train, and evaluate a variety of machine learning models”

Estimators Interface

The Estimators interface follows a train-evaluate-predict loop similar to scikit-learn. Estimator is the base class, pre-trained estimators (or pre-implemented models) are the sub-class.

The user specifies the meat of their model in a `model_fn`, using conditionals to denote behaviour that differs between TRAIN, EVALUATE and PREDICT. They add also a set of `input_fn` to describe how to handle data, optionally specifying them separately for training, evaluation, and prediction.

These functions are consumed by the `tf.estimator.Estimator` class to return an initialized estimator,

upon which we can call `.train`, `.eval`, and `.predict`.

Custom Estimator minimum layout

At a high level, the code will need to create a custom Estimator (`tf.estimator.Estimator`) will be:

A model function `model_fn` that is fed the features, labels and a few other parameters where your model code processes them and produces losses, metrics etc. The model function defines model, loss, optimizer, and metrics. This function has to return a `tf.estimator.EstimatorSpec`

Two input functions `input_fn` to feed the Estimators that returns features **and labels** for train and eval

An experiment object: to run the estimator in a configured state

other demos

I try to understand Bert better by looking at other demos using Bert but did not manage to understand much

Predicting Movie Reviews with BERT

I run this demo (in colab with TPU)

https://colab.research.google.com/github/google-research/bert/blob/master/predicting_movie_reviews_with_bert_on_tf_hub.ipynb

because I thought it could be fun to compare the predictions with the one that we got with simpler models than we have seen before, But the code seems to stay “for ever” (more than 3 hours in tpu) in the training phase. I did anyway put the code on github in case somewhere would be interested to look at.

```
estimator.train(input_fn=train_input_fn, max_steps=num_train_steps)
```

the last output line was

```
I0527 14:26:19.159367 139757240096640 basic_session_run_hooks.py:247] loss = 0.6038867, step = 101 (4532.371 sec)
```

The program never reaches the point when predictions are made

```
pred_sentences = [  
    "That movie was absolutely awful",  
    "The acting was a bit lacking",  
    "The film was creative and surprising",
```

```
"Absolutely fantastic!"  
]  
predictions = getPrediction(pred_sentences)
```

BERT End to End (Fine-tuning + Predicting)

The demo is about Sentence and Sentence-Pair Classification Tasks
and is found at

https://colab.research.google.com/github/tensorflow/tpu/blob/master/tools/colab/bert_finetuning_with_cloud_tpus.ipynb

but once more I did not understand and I did not put a copy on github

5.3. GAN

More interesting aspects of the code

In this section is a brief presentation of keras functions that I have not seen before and that were used in lab3_gan0

Leaky version of a Rectified Linear Unit.

<https://keras.io/layers/advanced-activations/>

`keras.layers.LeakyReLU(alpha=0.3)`

It allows a small gradient when the unit is not active: $f(x) = \alpha * x$ for $x < 0$, $f(x) = x$ for $x \geq 0$.

Class Conv2DTranspose

https://www.tensorflow.org/api_docs/python/tf/keras/layers/Conv2DTranspose

Transposed convolution layer (sometimes called Deconvolution).

The need for transposed convolutions generally arises from the desire to use a ***transformation going in the opposite direction of a normal convolution***, i.e., from something that has the shape of the output of some convolution to something that has the shape of its input while maintaining a connectivity pattern that is compatible with said convolution.

checkpoint

In train () you notice the use of checkpoint.save that is shortly presented here:

Checkpointing Neural Network Models

<https://machinelearningmastery.com/check-point-deep-learning-models-keras/>

Application checkpointing is a fault tolerance technique for long running processes.

It is an approach where a snapshot of the state of the system is taken in case of system failure.

If there is a problem, not all is lost. The checkpoint may be used directly, or used as the starting point for a new run, picking up where it left off.

When training deep learning models, the checkpoint is the weights of the model. These weights can be used to make predictions as is, or used as the basis for ongoing training.

<https://keras.io/callbacks/#modelcheckpoint>

```
keras.callbacks.ModelCheckpoint(filepath, monitor='val_loss', verbose=0, save_best_only=False,
save_weights_only=False, mode='auto', period=1)
```

about batchNormalization

<https://keras.io/layers/normalization/>

```
keras.layers.BatchNormalization(axis=-1, momentum=0.99, epsilon=0.001, center=True,
scale=True, beta_initializer='zeros', gamma_initializer='ones', moving_mean_initializer='zeros',
moving_variance_initializer='ones', beta_regularizer=None, gamma_regularizer=None,
beta_constraint=None, gamma_constraint=None)
```

Normalize the activations of the previous layer at each batch, i.e. *applies a transformation that maintains the mean activation close to 0 and the activation standard deviation close to 1.*
